PATENT US223898A

The problem

Traditional lighting methods often lacked the reliability or brightness needed for consistent illumination. There was a need for a practical electric light source that could operate effectively.

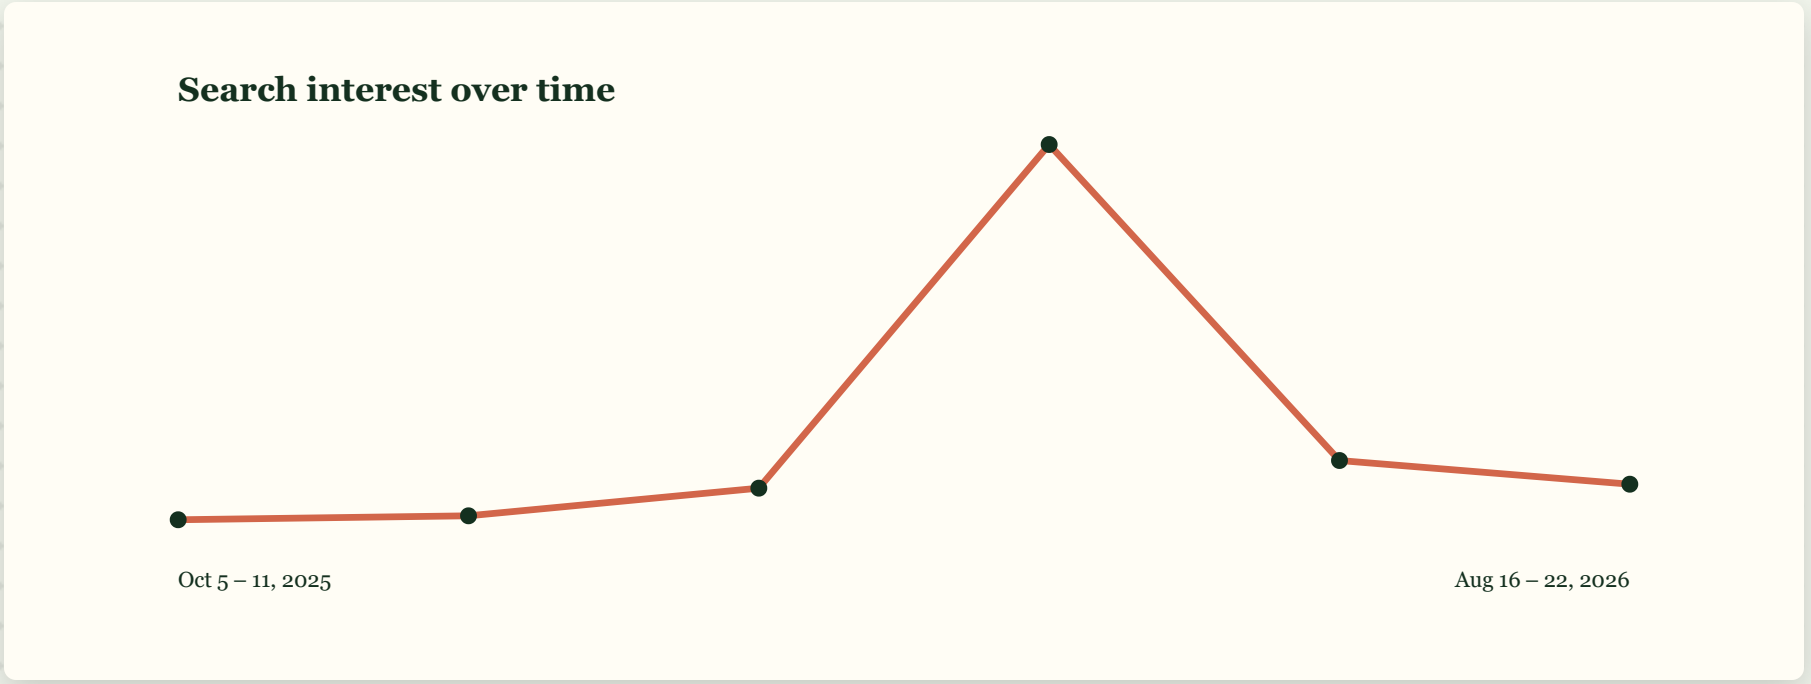

How it works

- An electric current is passed through a metallic filament.
- The electrical resistance causes the filament to heat up.
- The intense heat makes the metal glow brightly.
- This incandescent glow produces visible light.
- The lamp is powered by an external electrical source.

T. A. EDISON.
Electric-Lamp.
No. 223,898. Patented Jan. 27, 1880.

Why it matters

- Provides a practical and reliable source of artificial light.
- Enables illumination without the use of open flames or gas.
- Establishes a foundational technology for modern electric lighting.
